

Algorithm/Running Time Analysis

Running Time

- Why do we need to analyze the running time of a program?
- Option 1: Run the program and time it
 - Why is this option bad?
 - What can we do about it?

Pseudo-Code

- Used to specify algorithms
- Part English, part code

```
Algorithm (arrayMax(A, n))
curMax = A[0]
for i=1 i<n i++
    if curMax < A[i]
        curMax = A[i]
return curMax
```

Math Review

- Summation – \sum
- Sum of n consecutive digits = $n(n+1)/2$

Counting Operations

```
Algorithm (arrayMax(A, n))
curMax = A[0]//1
for i=1 i<n i++ //n
    //1 or 2
    if curMax < A[i]
        curMax = A[i]
return curMax //1
```

- Best case – $n+2$
- Worst case – $2n + 2$
- Average case – hard to analyze

Asymptotic Notation

- $2n + 2$
- $n=5 \rightarrow 12$
- $n=100 \rightarrow 202$
- $n=1,000,000 \rightarrow 2,000,002$
- Running time **grows proportionally** to n
- What happens as n gets large?

Big-Oh

- $f(n)$ is $O(g(n))$ if there is a real constant $c > 0$ and an integer constant $n_0 >= 1$ such that $f(n) <= cg(n)$ for every integer $n >= n_0$
- $2n+2$ is $O(n)$ $n_0 >= 1$ $c=3$

Examples

- $87n^4 + 7n$
- $3n \log n + 12 \log n$
- $4n^4 + 7n^3 \log n$

Terminology

- Logarithmic – $O(\log n)$
- Linear – $O(n)$
- Linearithmic – $O(n \log n)$
- Quadratic – $O(n^2)$
- Polynomial – $O(n^k)$ $k >= 1$
- Exponential – $O(a^n)$ $a > 1$

Example

	0			n-1
0	6	4	...	2
	12	3	...	9

n-1	5	8	...	1

- Find maximum number in $n \times n$ matrix
- Algorithm:

Example

- What is the big-oh running time of this algorithm?

```
Algorithm:
Input: A, n
curMax = A[0][0]
for i=0 i<n i++
  for j=0 j<n j++
    if curMax < A[i][j]
      curMax = A[i][j]
return curMax
```

Another Example

	0			n-1
	2	4	...	6
	6	8	...	3

- Determine how many elements of array 1 match elements of array 2
- Algorithm?

Another Example

0			n-1
2	4	...	6
0			n-1
6	8	...	3

Algorithm:

Input: A, B, n

```
for i=0 i<n i++
  for j=0 j<n j++
    if A[i] == A[j]
      matches++
      break
```

- What is the running time of the algorithm?
