

Internet Key Exchange (IKE)

EJ Jung
11/10/10

Secure Key Establishment

- Goal: generate and agree on a session key using some public initial information
- What properties are needed?
 - Authentication (know identity of other party)
 - Secrecy (generated key not known to any others)
 - Forward secrecy (compromise of one session key does not compromise keys in other sessions)
 - Prevent replay of old key material
 - Prevent denial of service
 - Protect identities from eavesdroppers
 - Other properties you can think of???

Key Management in IPSec

- Manual key management
 - Keys and parameters of crypto algorithms exchanged offline (e.g., by phone), security associations established by hand
- Pre-shared symmetric keys
 - New session key derived for each session by hashing pre-shared key with session-specific nonces
 - Standard symmetric-key authentication and encryption
- Online key establishment
 - Internet Key Exchange (IKE) protocol
 - Use Diffie-Hellman to derive shared symmetric key

Diffie-Hellman Key Exchange

Authentication?

No

Secrecy?

Only against passive attacker

Replay attack?

Vulnerable

Forward secrecy?

Yes

Denial of service?

Vulnerable

Identity protection?

Yes

Participants can't tell $g^x \bmod p$ from a random element of G : send them garbage and they'll do expensive exponentiations

IKE Genealogy

Design Objectives for Key Exchange

➤ Shared secret

- Create and agree on a secret which is known only to protocol participants

➤ Authentication

- Participants need to verify each other's identity

➤ Identity protection

- Eavesdropper should not be able to infer participants' identities by observing protocol execution

➤ Protection against denial of service

- Malicious participant should not be able to exploit the protocol to cause the other party to waste resources

Ingredient 1: Diffie-Hellman

A $\rightarrow$ B: g^a

B $\rightarrow$ A: g^b

- Shared secret is g^{ab} , compute key as $k = \text{hash}(g^{ab})$
 - Diffie-Hellman guarantees perfect forward secrecy
- Authentication
- Identity protection
- DoS protection

Ingredient 2: Challenge-Response

$A \rightarrow B: m, A$

$B \rightarrow A: n, \text{sig}_B(m, n, A)$

$A \rightarrow B: \text{sig}_A(m, n, B)$

- Shared secret
- Authentication
 - A receives his own number m signed by B's private key and deduces that B is on the other end; similar for B
- Identity protection
- DoS protection

DH + Challenge-Response

ISO 9798-3 protocol:

$A \rightarrow B: g^a, A$

$B \rightarrow A: g^b, \text{sig}_B(g^a, g^b, A)$

$A \rightarrow B: \text{sig}_A(g^a, g^b, B)$

$m := g^a$

$n := g^b$

- Shared secret: g^{ab}
- Authentication
- Identity protection
- DoS protection

Ingredient 3: Encryption

Encrypt signatures to protect identities:

$A \rightarrow B: g^a, A$

$B \rightarrow A: g^b, \text{Enc}_k(\text{sig}_B(g^a, g^b, A))$

$A \rightarrow B: \text{Enc}_k(\text{sig}_A(g^a, g^b, B))$

- Shared secret: g^{ab}
- Authentication
- Identity protection (for responder only!)
- DoS protection

$k = \text{hash}(g^{ab})$

Refresher: DoS Prevention

- Denial of service due to resource clogging
 - If responder opens a state for each connection attempt, attacker can initiate thousands of connections from bogus or forged IP addresses
- **Cookies** ensure that the responder is stateless until initiator produced at least 2 messages
 - Responder's state (IP addresses and ports) is stored in an unforgeable cookie and sent to initiator
 - After initiator responds, cookie is regenerated and compared with the cookie returned by the initiator
 - The cost is 2 extra messages in each execution

Storing Info Across Sessions

- A **cookie** is a file created by an Internet site to store information on your computer

HTTP is a stateless protocol; cookies add state

Refresher: Anti-DoS Cookie

➤ Typical protocol:

- Client sends request (message #1) to server
- Server sets up connection, responds with message #2
- Client may complete session or not (potential DoS)

➤ Cookie version:

- Client sends request to server
- Server sends hashed connection data back
 - Send message #2 later, after client confirms his address
- Client confirms by returning hashed data
- Need an extra step to send postponed message #2

Ingredient 4: Anti-DoS Cookie

“Almost-IKE” protocol:

A $\rightarrow$ B: g^a, A

B $\rightarrow$ A: $g^b, \text{hash}_{k_b}(g^b, g^a)$

A $\rightarrow$ B: $g^a, g^b, \text{hash}_{k_b}(g^b, g^a)$

$\text{Enc}_K(\text{sig}_A(g^a, g^b, B))$

B $\rightarrow$ A: $g^b, \text{Enc}_K(\text{sig}_B(g^a, g^b, A))$

Doesn't quite work: B must remember his DH exponent b for every connection

$k = \text{hash}(g^{ab})$

- Shared secret: g^{ab}
- Authentication
- Identity protection
- DoS protection?

Medium-Term Secrets and Nonces

- Idea: use the same Diffie-Hellman value g^{ab} for every session, update every 10 minutes or so
 - Helps against denial of service
- To make sure keys are different for each session, derive them from g^{ab} and session-specific nonces
 - Nonces guarantee freshness of keys for each session
 - Re-computing g^a , g^b , g^{ab} is costly, generating nonces (fresh random numbers) is cheap
- This is more efficient and helps with DoS, but no longer guarantees forward secrecy (why?)

(Simplified) Photuris

[Karn and Simpson]

IKE Genealogy Redux

Cookies in Photuris and ISAKMP

- Photuris cookies are derived from local secret, IP addresses and ports, counter, crypto schemes
 - Same (frequently updated) secret for all connections
- ISAKMP requires unique cookie for each connect
 - Add timestamp to each cookie to prevent replay attacks
 - Now responder needs to keep state ("cookie crumb")
 - Vulnerable to denial of service (why?)
- **Inherent conflict:** to prevent replay, need to remember values that you've generated or seen before, but keeping state allows denial of service

IKE Overview

- Goal: create **security association** between 2 hosts
 - Shared encryption and authentication keys, agreement on crypto algorithms
- **Two phases:** 1st phase establishes security association (IKE-SA) for the 2nd phase
 - Always by authenticated Diffie-Hellman (expensive)
- 2nd phase uses IKE-SA to create actual security association (child-SA) to be used by AH and ESP
 - Use keys derived in the 1st phase to avoid DH exchange
 - Can be executed cheaply in “quick” mode
 - To create a fresh key, hash old DH value and new nonces

Why Two-Phase Design?

- Expensive 1st phase creates “main” SA
- Cheap 2nd phase allows to create multiple child SAs (based on “main” SA) between same 2 hosts
 - Example: one SA for AH, another SA for ESP
 - Different conversations may need different protection
 - Some traffic only needs integrity protection or short-key crypto
 - Too expensive to always use strongest available protection
 - Avoid multiplexing several conversations over same SA
 - For example, if encryption is used without integrity protection (bad idea!), it may be possible to splice the conversations
 - Different SAs for different classes of service

IKE: Phase One

IKE: Phase Two (Create Child-SA)

After Phase One, I and R share key K

Can run this several times to create multiple SAs

Other Aspects of IKE

We did **not** talk about...

- Interaction with other network protocols
 - How to run IPSec through NAT (Network Address Translation) gateways?
- Error handling
 - Very important! Bleichenbacher attacked SSL by cryptanalyzing error messages from an SSL server
- Protocol management
 - Dead peer detection, rekeying, etc.
- Legacy authentication
 - What if one of the parties doesn't have a public key?

Current State of IPSec

- Best currently existing VPN standard
 - For example, used in Cisco PIX firewall, many remote access gateways
- IPSec has been out for a few years, but wide deployment has been hindered by complexity
 - ANX (Automotive Networking eXchange) uses IPSec to implement a private network for the Big 3 auto manufacturers and their suppliers
