14-0: Disjoint Sets

- Maintain a collection of sets
- Operations:
 - Determine which set an element is in
 - Union (merge) two sets
- Initially, each element is in its own set
 - # of sets = # of elements

14-1: Disjoint Sets

- Elements will be integers (for now)
- Operations:
 - CreateSets(n) Create n sets, for integers 0..(n-1)
 - Union(x,y) merge the set containing x and the set containing y
 - Find(x) return a representation of x's set
 - Find(x) = Find(y) iff x,y are in the same set

14-2: Disjoint Sets

- Implementing Disjoint sets
 - How should disjoint sets be implemented?

14-3: Implementing Disjoint Sets

- Implementing Disjoint sets (First Try)
 - Array of set identifiers:
 - Set[i] = set containing element i
 - Initially, Set[i] = i

14-4: Implementing Disjoint Sets

• Creating sets:

14-5: Implementing Disjoint Sets

• Creating sets: (pseudo-Java)

```
void CreateSets(n) {
   for (i=0; i<n; i++) {
      Set[i] = i;
   }
}</pre>
```

14-6: Implementing Disjoint Sets

• Find:

14-7: Implementing Disjoint Sets

```
• Find: (pseudo-Java)
```

```
int Find(x) {
    return Set[x];
}
```

14-8: Implementing Disjoint Sets

• Union:

14-9: Implementing Disjoint Sets

```
• Union: (pseudo-Java)
```

```
void Union(x,y) {
   set1 = Set[x];
   set2 = Set[y];
   for (i=0; i < n; i=+)
        if (Set[i] == set2)
            Set[i] = set1;
}</pre>
```

14-10: **Disjoint Sets** $\Theta()$

- CreateSets
- Find
- Union

14-11: **Disjoint Sets** $\Theta()$

- CreateSets: $\Theta(n)$
- Find: $\Theta(1)$
- Union: $\Theta(n)$

14-12: **Disjoint Sets** $\Theta()$

- CreateSets: $\Theta(n)$
- Find: $\Theta(1)$
- Union: $\Theta(n)$

We can do better! (At least for Union ...) 14-13: Implementing Disjoint Sets II

- Store elements in trees
- All elements in the same set will be in the same tree
- Find(x) returns the element at the root of the tree containing x

• How can we easily find the root of a tree containing x?

14-14: Implementing Disjoint Sets II

- Store elements in trees
- All elements in the same set will be in the same tree
- Find(x) returns the element at the root of the tree containing x
 - How can we easily find the root of a tree containing x?
 - Implement trees using parent pointers instead of children pointers

14-15: Trees Using Parent Pointers

• Examples:

14-16: Implementing Disjoint Sets II

- Each element is represented by a node in a tree
- Maintain an array of pointers to nodes

14-17: Implementing Disjoint Sets II

- Each element is represented by a node in a tree
- Maintain an array of pointers to nodes

14-18: Implementing Disjoint Sets II

• Find:

14-19: Implementing Disjoint Sets II

- Find:
 - Follow parent pointers, until root is reached.
 - Root is node with null parent pointer.
 - Return element at root

14-20: Implementing Disjoint Sets II

• Find: (pseudo-Java)

```
int Find(x) {
   Node tmp = Sets[x];
   while (tmp.parent != null)
      tmp = tmp.parent;
   return tmp.element;
}
```

14-21: Implementing Disjoint Sets II

• Union(x,y)

14-22: Implementing Disjoint Sets II

- Union(x,y)
 - Calculate:
 - Root of x's tree, rootx
 - Root of y's tree, rooty
 - Set parent(rootx) = rooty

14-23: Implementing Disjoint Sets II

• Union(x,y) (pseudo-Java)

```
void Union(x,y) {
  rootx = Find(x);
  rooty = Find(y);
  Sets[rootx].parent = Sets[rooty];
}
```

14-24: Removing pointers

- We don't need any pointers
- Instead, use index into set array

• Union(2,3), Union(6,8), Union(0,2), Union(2,6)

14-26: Removing pointers

• Union(2,3), Union(6,8), Union(0,2), Union(2,8)

14-27: Implementing Disjoint Sets III

• Find: (pseudo-Java)

```
int Find(x) {
   while (Parent[x] != -1)
        x = Parent[x]
   return x
}
```

14-28: Implementing Disjoint Sets II

• Union(x,y) (pseudo-Java)

```
void Union(x,y) {
   rootx = Find(x);
   rooty = Find(y);
   Parent[rootx] = rooty;
}
```

CS245-2015S-14

Disjoint Sets

14-29: Efficiency of Disjoint Sets II

- So far, we haven't done much to improve the run-time efficiency of Disjoint sets.
- Two improvements will make a huge difference:
 - Union by rank
 - Path compression

14-30: Union by Rank

- When we merge two sets:
 - "Shorter" tree point to the taller tree

14-31: Union by Rank

- We need to keep track of the height of each tree
- How?

14-32: Union by Rank

- We need to keep track of the height of each tree
 - Store the height of the tree at the root
 - If a node x is not a root, Parent[x] = parent of x
 - If a node x is a root, Parent[x] = 0 # height of tree rooted at x

14-33: Union by Rank

• Examples

14-34: Union by Rank

• When we merge two trees, how do we know which tree to point at the other?

14-35: Union by Rank

- When we merge two trees, how do we know which tree to point at the other?
 - The node with the larger (less negative) Parent[] value points to the node with the smaller (more negative) Parent[] value. Break ties arbitrarily.
- How do we update the height of the new merged tree?

14-36: Union by Rank

- When we merge two trees, how do we know which tree to point at the other?
 - The node with the larger (less negative) Parent[] value points to the node with the smaller (more negative) Parent[] value. Break ties arbitrarily.
- How do we update the height of the new merged tree?
 - If trees are different sizes, do nothing

• If trees are the same size, increase (decrease) new parent by 1.

14-37: Union by Rank

• Union(x,y) (pseudo-Java)

```
void Union(x,y) {
  rootx = Find(x);
  rooty = Find(y);
  if (Parent[rootx] < Parent[rooty]) {
    Parent[rooty] = x;
  } else {
    if Parent[rootx] == Parent[rooty]
        Parent[rooty]--;
    Parent[rootx] = rooty;
  }
}</pre>
```

14-38: Path Compression

- After each call to Find (x), change x's parent pointer to point directly at root
- Also, change all parent pointers on path from x to root

14-39: Implementing Disjoint Sets III

```
• Find: (pseudo-Java)
```

```
int Find(x) {
    if (Parent[x] < 0)
        return x;
    else {
        Parent[x] = Find(Parent[x]);
        return Parent[x];
    }
}</pre>
```

14-40: **Disjoint Set** Θ

- Time to do a Find / Union proportional to the depth of the trees
- "Union by Rank" tends to keep tree sizes down
- "Path compression" makes Find and Union causes trees to flatten
- Union / Find take roughly time O(1) on average

14-41: **Disjoint Set** Θ

- Technically, n Find/Unions take time $O(n \lg^* n)$
- $\lg^* n$ is the number of times we need to take \lg of n to get to 1.
 - $\lg 2 = 1, \lg^* 2 = 1$
 - $\lg(\lg 4) = 1, \lg^* 4 = 2$

- $\lg(\lg(\lg 16)) = 1, \lg^* 16 = 3$
- $\lg(\lg(\lg(\lg 65536))) = 1, \lg^* 65536 = 4$
- ...
- $\lg^* 2^{65536} = 5$
- + # of atoms in the universe $\approx 10^{80} \ll 2^{65536}$
- $\lg^* n \le 5$ for all practical values of n
